Statistics: Homework 1

1.19 Let X_1, X_2 and X_3 denote the computer owners that use Macintosh, Windows and Linux respectively and let V denote the event that the user's system is infected with the virus. We want to find $\mathbb{P}(X_2|V)$

$$\mathbb{P}(X_2|V) = \frac{\mathbb{P}(V|X_2)\mathbb{P}(X_2)}{\sum_{i=1}^{3} \mathbb{P}(V|X_i)\mathbb{P}(X_i)}$$
$$= \frac{(.82)(.5)}{(.65)(.3) + (.82)(.5) + (.5)(.2)}$$
$$= 0.581560284$$

2.4 (a)

$$F_X(x) := \begin{cases} \frac{1}{4}x & 0 < x < 1\\ \frac{3}{8}x - \frac{7}{8} & 3 < x < 5\\ 1 & x > 5 \end{cases}$$

(b)

$$\begin{split} \mathbb{P}(Y \leq y) &= \mathbb{P}(1/X \leq y) \\ &= \mathbb{P}(X \geq 1/y) \\ &= 1 - \mathbb{P}(X \leq 1/y) \end{split}$$

From (a):

$$F_Y(y) := \begin{cases} \frac{15}{8} - \frac{3}{8y} & 1/5 < y < 1/3\\ 1 - \frac{1}{4y} & y \ge 1\\ 0 & \text{otherwise} \end{cases}$$

$$f_Y(y) := \begin{cases} \frac{3}{8y^2} & 1/5 < y < 1/3\\ \frac{1}{4y^2} & y \ge 1\\ 0 & \text{otherwise} \end{cases}$$

2.11 (a) We see that $\mathbb{P}(X=1)=p=\mathbb{P}(Y=0)$. Since the state space contains $\{H,T\}$, we have $1-\mathbb{P}(X=1,Y=0)=1-p=\mathbb{P}(X=0,Y=1)$. But since

$$\mathbb{P}(X=1)\mathbb{P}(Y=0) = p^2 \neq p = \mathbb{P}(X=1, Y=0)$$

X and Y are dependent.

(b) By total law of probability,

$$\mathbb{P}(X = x) = \sum_{n=x}^{\infty} \mathbb{P}(X = x | N = n) \cdot \mathbb{P}(N = n)$$

$$= \sum_{n=x}^{\infty} \binom{n}{x} p^x (1 - p)^{n-x} \cdot e^{-\lambda} \frac{\lambda^n}{n!}$$

$$= e^{-\lambda} \frac{(\lambda p)^x}{x!} \sum_{n=x}^{\infty} \frac{[\lambda (1 - p)]^{n-x}}{(n - x)!}$$

$$= e^{-\lambda p} \frac{(\lambda p)^x}{x!}$$

in a similar fashion, we have

$$\mathbb{P}(Y = y) = e^{-\lambda(1-p)} \frac{(\lambda(1-p))^y}{y!}$$

for the joint distribution of X and Y,

$$\mathbb{P}(X = x, Y = n - x) = \mathbb{P}(X = x, Y = n - x | N = n) \cdot \mathbb{P}(N = n)$$
$$= \binom{n}{x} p^x (1 - p)^{n - x} \cdot e^{-\lambda} \frac{\lambda^n}{n!}$$

now

$$\mathbb{P}(X=x) \cdot \mathbb{P}(Y=y) = e^{-\lambda p} \frac{(\lambda p)^x}{x!} \cdot e^{-\lambda(1-p)} \frac{(\lambda(1-p))^y}{y!}$$
$$= {x+y \choose x} p^x (1-p)^y e^{-\lambda} \frac{\lambda^{x+y}}{(x+y)!}$$

which shows that X and Y are independent.

3.4 Let Y_i denote the jump of the particle at the *i*th unit. Then $X_n = \sum_{i=1}^n Y_i$. The Y_i 's are iid, with $\mathbb{E}(Y_i) = 1 - 2p$ and $\mathbb{V}(Y_i) = 1 - (1 - 2p)^2 = 4p(1 - p)$ for i = 1, 2, ..., n.

$$\mathbb{E}(X_n) = \sum_{i=1}^n \mathbb{E}(Y_i) = n(1 - 2p)$$

$$\mathbb{V}(X_n) = \sum_{i=1}^n \mathbb{V}(Y_i) = n \cdot 4p(1 - p)$$

4.3 Using Chebyshev's and Hoeffding's inequality we have

$$\mathbb{P}(|\overline{X}_n - p| > \epsilon) \le \frac{1}{4n\epsilon^2}$$

$$\mathbb{P}(|\overline{X}_n - p| > \epsilon) \le 2e^{-2n\epsilon^2}$$

The inequality $(1+x)^r \le e^{rx}$ for r > 0, x > 0, thus for r = 1

$$x < 1 + x \le e^{x}$$

$$1/x > e^{-x}$$

$$\frac{1}{2n\epsilon^{2}} > e^{-2n\epsilon^{2}}$$

$$\frac{1}{n\epsilon^{2}} > 2e^{-2n\epsilon^{2}}$$

5.7 We first note that

$$\mathbb{V}\left(n^{-1}\sum_{i=1}^{n}X_{i}^{2}-p\right)=n^{-2}\sum_{i=1}^{n}\mathbb{V}(X_{i}^{2})=\frac{p(1-p)}{n}$$

thus for any given $\epsilon > 0$,

$$\mathbb{P}\left(|n^{-1}\sum_{i=1}^{n}X_{i}^{2}-p|>\epsilon\right)\leq \frac{\mathbb{V}(n^{-1}\sum_{i=1}^{n}X_{i}^{2}-p)}{\epsilon^{2}}=\frac{p(1-p)}{n\epsilon^{2}}\to 0 \text{ as } n\to\infty$$

which proves the convergence in probability. We now prove its convergence in quadratic mean:

$$\mathbb{E}\left(\left[n^{-1}\sum_{i=1}^{n}X_{i}^{2}-p\right]^{2}\right)=\mathbb{E}\left(n^{-2}\left[\sum_{i=1}^{n}X_{i}^{2}\right]^{2}\right)-2\mathbb{E}\left(p/n\sum_{i=1}^{n}X_{i}^{2}\right)+\mathbb{E}\left(p^{2}\right)$$
(1)

simplifying the first term, we get

$$\begin{split} \mathbb{E}\left(n^{-2}\left[\sum_{i=1}^{n}X_{i}^{2}\right]^{2}\right) &= n^{-2}\left[\mathbb{E}\left(\sum_{i=1}^{n}X_{i}^{4}\right) + 2\,\mathbb{E}\left(\sum_{i\neq j}X_{i}^{2}X_{j}^{2}\right)\right] \\ &= n^{-2}\left[\mathbb{E}\left(\sum_{i=1}^{n}X_{i}^{4}\right) + 2\,\sum_{i\neq j}\mathbb{E}\left(X_{i}^{2}\right)\,\mathbb{E}\left(X_{j}^{2}\right)\right] \\ &= n^{-2}\left[np + 2\binom{n}{2}p^{2}\right] \\ &= \frac{p}{n} + \frac{n-1}{n}p^{2} \end{split}$$

the simplification of the last 2 terms in $(\ref{eq:condition})$ gives $-p^2$. Thus

$$\mathbb{E}\left(\left[n^{-1}\sum_{i=1}^{n}X_{i}^{2}-p\right]^{2}\right) = \frac{p-p^{2}}{n} \to 0 \text{ as } n \to \infty$$

which concludes the prove of convergence in quadratic mean.
