Statistics: Homework 2

6.3 Given $\hat{\theta} = 2\overline{X}_n$ and $X_1, \ldots, X_n \sim \text{Uniform}(0, \theta)$,

$$\text{bias}(\hat{\theta}) = \mathbb{E}(2\overline{X}_n) - \theta$$
$$= 2n^{-1}\mathbb{E}\left(\sum_{i=1}^{n} X_i\right) - \theta$$
$$= 2n^{-1}\sum_{i=1}^{n} \mathbb{E}(X_i) - \theta$$
$$= 2n^{-1}\frac{n\theta}{2} - \theta = 0$$
$$\text{se}(\hat{\theta})^2 = \mathbb{V}(2\overline{X}_n)$$
$$= 4\mathbb{V}(\overline{X}_n)$$
$$= 4n^{-2}\mathbb{V}\left(\sum_{i=1}^{n} X_i\right)$$
$$= 4n^{-2}\sum_{i=1}^{n} \mathbb{V}(X_i)$$
$$= 4n^{-2}\frac{n\theta^2}{12} = \frac{\theta^2}{3n}$$
$$\text{MSE}(\hat{\theta}) = \text{bias}(\hat{\theta})^2 + \text{se}(\hat{\theta})^2 = \frac{\theta^2}{3n}$$

7.2 For $X_1, \ldots, X_n \sim \text{Bernoulli}(p)$ plug-in estimator for p is

$$\hat{p} = \frac{1}{n}\sum_{i=1}^{n} X_i$$

and the estimated standard error is given by

$$\hat{\text{se}}_p = \sqrt{\mathbb{V}(\hat{p})} = \sqrt{\frac{\hat{p}(1-\hat{p})}{n}}$$

As the X_i's are iid, by Central Limit Theorem, $\hat{p}$ is asymptotically normal with mean p and variance $\hat{\text{se}}_p^2$. Thus an approximate 90% confidence interval for p is $(\hat{p} - 1.96\text{se}, \hat{p} + 1.96\text{se})$.

For $X_1, \ldots, X_n \sim \text{Bernoulli}(p)$ and $Y_1, \ldots, Y_n \sim \text{Bernoulli}(q)$ plug-in estimator for $p - q$ is

$$\hat{p} - \hat{q} = \frac{1}{n}\sum_{i=1}^{n} X_i - \frac{1}{m}\sum_{i=1}^{m} Y_i$$

with estimated standard error

$$\hat{\text{se}}_{p-q} = \sqrt{\mathbb{V}(\hat{p} - \hat{q})} = \sqrt{\mathbb{V}(\hat{p}) + \mathbb{V}(\hat{q})} = \sqrt{\frac{\hat{p}(1-\hat{p})}{n} + \frac{\hat{q}(1-\hat{q})}{m}}$$

Since the Y_i's are iid, by Central Limit Theorem $\hat{q}$ is asymptotically normal with mean q and variance $\hat{\text{se}}_q^2$. The difference of two asymptotically normal random variables is asymptotically normal, thus $p \hat{-} q$ is asymptotically normal with mean $p - q$ and variance se_{p-q}^2. An approximate 90% confidence interval is

$$\text{se}_{p-q} = (\hat{p} - \hat{q} - 1.96\text{se}_{p-q}, \hat{p} - \hat{q} + 1.96\text{se}_{p-q})$$

7.9 An estimate for $p_1 - p_2$ is $0.9 - 0.85 = 0.05$ with standard error

$$\sqrt{\frac{0.9(1-0.9)}{100} + \frac{0.85(1-0.85)}{100}} = 0.0466368953$$

with 80% and 90% confidence intervals given by

$$80\%: \quad (\hat{p} - \hat{q} - 1.282\text{se}_{p-q}, \hat{p} - \hat{q} + 1.282\text{se}_{p-q}) = (-0.0097885, 0.1097885)$$
$$90\%: \quad (\hat{p} - \hat{q} - 1.96\text{se}_{p-q}, \hat{p} - \hat{q} + 1.96\text{se}_{p-q}) = (-0.041408315, 0.141408315)$$
